## 1. INTRODUCTION

Real-Time Traffic Object Detection and Data Analysis is a dashboard project designed to monitor and analyze traffic objects in real-time. The system uses advanced object detection techniques to identify and count various objects, including vehicles, pedestrians, and animals. The count, along with the object's class name and timestamp, is stored in a database for further analysis. The collected data is visualized on a comprehensive dashboard through a variety of graphs and charts, providing insights into traffic patterns. The dashboard includes features such as daily, weekly, and monthly reports, as well as traffic density analysis in specific regions. This helps identify bottlenecks, high-traffic zones, and areas requiring interventions for better traffic management. This system also gives an alert if it detects any kind of animal on the road, enhancing safety measures.

Current traffic monitoring systems primarily use surveillance cameras, inductive loop detectors, and radar-based sensors. Surveillance cameras capture video footage for manual monitoring, while inductive loop detectors embedded in roads detect vehicles based on electromagnetic changes. Radar-based systems provide speed and vehicle detection for specific areas. Although effective to some extent, these systems face several limitations, including the inability to classify objects into categories such as vehicles, pedestrians, or animals, lack of real-time analytics, and a reliance on manual intervention for data analysis. Furthermore, these systems are often limited in scalability and integration with advanced traffic management solutions, highlighting the need for more automated and comprehensive approaches.

The proposed system, Real-Time Traffic Object Detection and Data Analysis, leverages advanced technologies to address the limitations of existing traffic monitoring systems. Using YOLOv8 for object detection, the system identifies and classifies various objects, such as vehicles, pedestrians, and animals, in real time. The detected objects are counted, and their data, including class names and timestamps, is stored in a database for analysis. A dynamic dashboard powered by Power BI visualizes this data through interactive graphs and charts, offering insights into traffic patterns with daily, weekly, and monthly reports. The system also identifies high-traffic zones and bottlenecks, providing actionable insights for traffic management and urban planning. Additionally, a safety alert mechanism triggers immediate notifications upon detecting animals on the road, enhancing road safety.

The project will use Python for backend development, with Flask as the web framework. MySQL will store object data, including class names, counts, and timestamps. For object detection and classification, the system will leverage the pre-trained YOLOv8 model, with OpenCV integrated for real-time image processing. The front-end will be designed using HTML, CSS, and Bootstrap for a responsive user interface, while the Power BI dashboard will provide interactive and dynamic visualizations of traffic patterns.

The Real-Time Traffic Object Detection and Data Analysis project presents a modern, efficient, and scalable solution for addressing the challenges of current traffic monitoring systems. By integrating advanced technologies such as YOLOv8 for object detection, OpenCV for image processing, Flask for backend development, and Power BI for dynamic dashboard visualization, the system ensures real-time analysis of traffic patterns with enhanced accuracy and usability. The inclusion of a safety alert mechanism for animal detection further emphasizes the system's focus on road safety. With features like object classification, timestamped data storage, and comprehensive traffic insights, this project not only streamlines traffic management but also lays the groundwork for future smart city applications.

## 2. SUPPORTING LITERATURE

### 2.1 LITERATURE REVIEW

**Paper 1:** M. Hussain, "YOLOv1 to v8: Unveiling Each Variant—A Comprehensive Review of YOLO," in *IEEE Access*, vol. 12, pp. 42816-42833, 2024, doi: 10.1109/ACCESS.2024.3378568.

The paper titled "YOLOv1 to v8: Unveiling Each Variant—A Comprehensive Review of YOLO" presents a thorough analysis of the evolutionary advancements across the YOLO object detection series. It systematically reviews the architectural innovations, training strategies, and real-world applications of YOLO, starting from its inception with YOLOv1 in 2016 to the latest YOLOv8, released in 2023. Each variant's contributions, such as improved accuracy, speed, and adaptation to diverse domains, are discussed comprehensively, showcasing YOLO's role in driving advancements in real-time object detection.

The study highlights YOLO’s impact across various sectors, including surveillance, autonomous vehicles, healthcare, and environmental monitoring. It underscores the incremental improvements in model architecture, such as the introduction of anchor boxes, multi-scale detection, and advanced loss functions, which have enhanced YOLO's ability to handle challenges like occlusions, scale variations, and real-time constraints. Future directions are proposed, focusing on integrating YOLO with federated learning and edge deployment to enhance privacy, adaptability, and efficiency.

In conclusion, the review provides a complete roadmap of YOLO’s transformation, emphasizing its pioneering role in the domain of computer vision. The paper's critical evaluation of YOLO’s limitations and suggestions for future research make it a valuable resource for the development of advanced object detection systems.

**Paper 2: H. Naeem, J. Ahmad and M. Tayyab, "Real-time object detection and tracking," *INMIC*, Lahore, Pakistan, 2013, pp. 148-153, doi: 10.1109/INMIC.2013.6731341**

The paper titled "Real-Time Object Detection and Tracking System for Video Surveillance System" presents an innovative approach to real-time video surveillance, focusing on the challenges of object detection in low-end edge computing environments. The authors propose a novel algorithm, N-YOLO, which improves upon traditional YOLO by dividing images into fixed-sized sub-images instead of resizing them. This method enhances detection accuracy while maintaining computational efficiency. The system integrates object detection with a correlation-based tracking algorithm, ensuring high performance and scalability for edge devices.

The proposed N-YOLO algorithm achieves significant improvements in real-time applications by addressing limitations of conventional YOLO, such as detecting objects across sub-image boundaries. It leverages adaptive tracking intervals and efficient bounding box merging to improve throughput and accuracy. Additionally, the system demonstrates scalability for video surveillance in resource-constrained environments, making it ideal for edge computing applications without reliance on high-end GPUs.

Experimental results validate the effectiveness of the approach, showing better accuracy, F1 scores, and IoU values compared to YOLOv3. The proposed system is also robust in handling various video resolutions, delivering up to 50 FPS on low-end hardware. Future work aims to enhance re-identification capabilities and optimize loss functions for improved performance in real-time applications.

The paper titled "Big Data Analytics and Visualization in Traffic Monitoring" introduces the Trafair Traffic Dashboard (TTD), a visual analytics platform designed to monitor urban traffic and analyze its environmental impact, particularly on air quality. The dashboard uses real-time and historical traffic data collected via sensors and incorporates simulation models for traffic flow and air pollution dispersion. By visualizing trends, anomalies, and spatio-temporal patterns, the system supports decision-making for sustainable urban planning.

The Trafair project integrates various data sources, including traffic sensors, simulation outputs, and environmental models, to provide insights into traffic dynamics and pollution levels in urban areas. Key features include geospatial visualization, anomaly detection, and predictive modeling. The dashboard demonstrates its capabilities through case studies in Modena, Italy, and Santiago de Compostela, Spain, highlighting the system's adaptability and scalability for smart city applications.

Experimental results show the dashboard's ability to identify congestion, evaluate sensor reliability, and predict the impact of different vehicle fleets on air quality. The platform's reliance on open-source tools ensures cost-effectiveness and reproducibility across different urban scenarios, with future enhancements planned for database efficiency and hierarchical visualizations.

The paper titled "Visual Big Data Analytics for Traffic Monitoring in Smart City" presents a framework for detecting traffic violations, specifically targeting bike riders without helmets, using video surveillance data. This system leverages visual big data analytics to process and analyze large-scale video footage in real-time for semantic pattern recognition, addressing challenges like occlusion, motion direction, and environmental changes. The proposed method uses a two-phase approach: detecting bike riders and determining helmet usage by analyzing features from video frames.

The framework employs visual computing techniques for feature extraction and classification, integrating Histogram of Oriented Gradients (HOG), Scale-Invariant Feature Transform (SIFT), and Local Binary Patterns (LBP) for object detection and classification. A Support Vector Machine (SVM) classifier, combined with distributed cloud computing, ensures scalability and efficiency, enabling real-time processing of surveillance video data. The proposed solution uses a hybrid cloud model to manage computationally intensive tasks and storage, optimizing costs and performance.

Experimental results demonstrate high accuracy rates, achieving 98.88% for bike-rider detection and 93.80% for helmet violation detection. The system processes video frames in approximately 11 milliseconds, suitable for real-time applications. The study highlights the potential of visual big data frameworks in smart city applications, offering a scalable, robust, and cost-effective solution for traffic monitoring.

Two-phase method with HOG and SVM.  | Precision: 93.80%   |

## 2.3 Summary

| Title   | Summary   |
|---------|---|
| Paper 1 | <p>The paper comprehensively reviews YOLO object detection models from v1 to v8, focusing on the evolution of algorithms and architectural improvements. Each version is analyzed for its advancements, such as anchor boxes in YOLOv2, multi-scale detection in YOLOv3, and anchor-free modeling in YOLOv8. The review highlights YOLO's balance of speed and accuracy, making it highly relevant for real-time applications in areas like surveillance, autonomous vehicles, and healthcare. While the advancements improve precision, challenges like handling small objects persist. The models achieve mAP scores ranging from 63.4% to 57.9%, with FPS varying based on complexity, ensuring efficient real-time performance.</p> |
| Paper 2 | <p>This paper proposes the N-YOLO algorithm, which enhances traditional YOLO by segmenting images into fixed-size sub-images, improving detection accuracy for edge devices. Integrated with a correlation-based tracking system, the method achieves real-time detection with up to 93.80% accuracy for identifying helmet violations. The algorithm balances computational efficiency with robustness, making it ideal for low-resource environments like traffic surveillance. Limitations include potential false positives in highly cluttered scenes. The relevance lies in its applicability to scalable, real-time monitoring systems for public safety.</p>  |
| Paper 3 | <p>This study presents the Trafair Traffic Dashboard, a visual analytics tool for urban traffic and air quality monitoring. By integrating traffic sensor data, anomaly detection, and simulation models, the dashboard provides actionable insights into congestion patterns and environmental impacts. Algorithms like STL for anomaly detection and DTW for time-series alignment support robust analysis. The system demonstrates practical relevance in smart city applications, offering real-time updates and historical data comparison. The use of open-source tools ensures adaptability and cost-effectiveness. Limitations include occasional delays in data rendering due to complex queries.</p>                          |
| Paper 4 | <p>The paper introduces a two-phase system for detecting bike riders without helmets using surveillance video data. The approach employs background subtraction, feature extraction (HOG, SIFT, LBP), and SVM classification, achieving 98.88% accuracy for bike detection and 93.80% for helmet violation detection. The framework demonstrates real-time processing efficiency at ~11 ms per frame and is computationally scalable due to its cloud-based design. While effective, the reliance on video quality and environmental factors can affect performance. Its relevance is underscored by its potential to automate traffic rule enforcement in smart cities.</p>  |

### 3. PROJECT PROPOSAL

From the above-reviewed papers, we gain insights into various models, methodologies, and tools for real-time traffic monitoring, object detection, and data visualization. Inspired by these works, I propose developing a Real-Time Traffic Monitoring and Analysis Dashboard that combines object detection, traffic flow analysis, and monitoring for smart city applications. This comprehensive solution aims to address challenges such as traffic congestion, environmental impact, and urban safety by leveraging cutting-edge technologies and best practices from the reviewed studies.

The proposed dashboard will utilize YOLOv8 for real-time object detection, Python for data processing, and MySQL for efficient data storage and retrieval. To ensure an interactive and user-friendly experience, advanced visualization tools like Power BI or Tableau will be incorporated. These tools will provide dynamic dashboards to display key metrics, such as traffic density, congestion hotspots. The integration of these components is inspired by the approaches discussed in the papers, ensuring robustness and scalability.

From the first paper, I was inspired by YOLO's iterative advancements, particularly YOLOv8's anchor-free modeling and real-time performance. This forms the backbone of the proposed system, enabling accurate detection and classification of objects such as vehicles, pedestrians, and road signs. The second paper's insights into enhancing detection accuracy by segmenting images into sub-parts influenced the handling of complex scenarios, such as crowded intersections or occluded objects. These features ensure high accuracy and efficiency in real-time monitoring.

The third paper provided insights into integrating spatial and temporal data for traffic flow analysis. Algorithms such as Dynamic Time Warping (DTW) and Seasonal-Trend Decomposition (STL) will inspire the system's ability to recognize patterns, identify anomalies, and predict congestion trends. Additionally, the Trafair Traffic Dashboard discussed in the fourth paper highlighted the importance of incorporating air quality monitoring alongside traffic data. This dual focus enhances the relevance of the dashboard by offering environmental impact assessments alongside real-time traffic visualization.

The proposed system architecture includes YOLOv8 for object detection and classification, Python for data ingestion and preprocessing, and MySQL as the central database for storing traffic sensor data, detected object counts, and historical trends. The visualization layer, built using Power BI or Tableau, will display real-time traffic metrics, congestion heatmaps.

The expected outcomes of this project include accurate detection and classification of traffic density, vehicles, and congestion patterns using YOLOv8. The dashboard will provide data-driven insights, highlighting peak traffic times, high-density zones. This project aligns with smart city initiatives by offering actionable insights for traffic management, and urban safety enhancements.

## 4. ANALYSIS OF ALGORITHM

### 4.1 Object Detection with YOLOv8

YOLOv8 is a state-of-the-art object detection algorithm optimized for real-time applications. Here's how it works:

- **Approach:** YOLOv8 performs both object localization and classification simultaneously in one forward pass. It divides the input image into a grid and for each grid cell, it predicts bounding boxes and class probabilities. The model is trained to detect various traffic-related objects, such as vehicles, pedestrians, road signs, and animals.
- **Time Complexity:** The time complexity of YOLOv8 can be considered as  $O(n)O(n)O(n)$ , where  $n$  is the number of objects detected in the image. Since YOLOv8 processes the image in a single pass, it is faster compared to algorithms like Faster R-CNN, which require multiple passes through the image.
- **Space Complexity:** The space complexity is primarily determined by the size of the model (i.e., the number of parameters and the size of the feature maps). YOLOv8 is optimized to be more compact than previous YOLO versions, making it suitable for real-time applications even on hardware with limited resources.
- **Detection Speed:** YOLOv8 is designed to perform real-time object detection, making it ideal for traffic monitoring applications. It can process frames at a high rate (up to 60 FPS or more, depending on the hardware), ensuring that traffic objects are detected in real time.
- **Accuracy:** YOLOv8 is known for high accuracy and speed. It performs well in detecting various objects, even in challenging conditions like crowded scenes, occlusions, or varying lighting. However, the accuracy can be influenced by factors like the quality of the training data, the resolution of the input images, and the environment in which it is deployed (e.g., urban roads vs. highways).
- **Limitations:**
  - **Small Object Detection:** YOLOv8, like other YOLO versions, may struggle with detecting very small objects, such as pedestrians in a crowded scene.
  - **Occlusions:** Although YOLOv8 is optimized for handling occlusions to some extent, complex occlusions, like vehicles blocking pedestrians, may still result in missed detections.

### 4.2 Data Analysis and Visualization with Power BI

After detecting objects in real time, the system will analyze traffic patterns and visualize them for traffic authorities using Power BI. Here's how this part of the algorithm works:

- **Data Collection:** The traffic data, including object counts (vehicles, pedestrians, road signs, etc.), is stored in a MySQL database. The data is continuously updated as the YOLOv8 model processes each frame of the video feed.
- **Data Processing:** The algorithm processes the data by aggregating it (e.g., counting vehicle types, categorizing traffic density, tracking pedestrian numbers) and organizing it into formats suitable for visualization.
- **Time Complexity:** The time complexity of data processing is generally  $O(m)O(m)O(m)$ , where  $m$  is the number of data points (e.g., the number of detected objects). The data processing steps (aggregation, categorization) are efficient, but the time taken can grow with the volume of data being tracked, such as the number of vehicles in an entire city.

- **Space Complexity:** The space complexity depends on how much historical data is stored and how large the datasets are. Since Power BI queries the MySQL database and retrieves the necessary data for visualization, storage space and query efficiency are crucial for ensuring real-time performance.
- **Visualization:** Power BI allows for the creation of real-time dashboards. The algorithm continuously streams processed data (e.g., number of vehicles, pedestrian counts, etc.) to Power BI, which then visualizes this data using graphs, charts, and maps. The algorithm ensures that these visualizations are updated in real time, providing instant insights into traffic conditions.
- **Efficiency:** Power BI's data processing is highly efficient, especially when dealing with large datasets. However, the visualization part can be resource-intensive, especially when numerous data points are continuously updated. Optimization techniques like data aggregation, filtering, and using incremental data updates can mitigate this.

### 4.3 Real-Time System Integration

The integration of YOLOv8 for object detection with Power BI for analysis and reporting forms the core of the system. Here's a breakdown of how the real-time system performs:

- **End-to-End Latency:** The key performance indicator for this system is end-to-end latency, which is the total time taken from detecting an object in the video feed to displaying the results on the Power BI dashboard. The latency depends on several factors:
  - **Detection Time:** YOLOv8 processes each frame in a fraction of a second, typically within 40–100ms, depending on hardware.
  - **Data Processing Time:** After detection, the data is processed and inserted into the database. This step is quick but may add a small delay depending on the volume of traffic data.
  - **Visualization Time:** Power BI retrieves and updates the dashboard. Since Power BI operates in real-time, the system can visualize data almost immediately after it is processed.
- **Real-Time Performance:** The system is optimized for real-time performance. YOLOv8 provides instant object detection, while Power BI provides real-time updates. The overall system performs efficiently enough to monitor traffic in real time, with delays typically in the range of a few seconds.

## 5. DATASET EXPLORATION

Dataset exploration is a critical step in understanding the characteristics of the data, ensuring its quality, and identifying any preprocessing or cleaning steps needed before feeding it into the machine learning and analysis pipeline. In the case of your **Real-Time Traffic Object Detection and Analysis** project, the dataset would primarily consist of images or videos of road traffic, with labeled data for various objects like vehicles, pedestrians, road signs, and animals. Here's a detailed exploration of the dataset:

### 5.1 Dataset Overview

The dataset for real-time traffic object detection typically includes images or video frames captured from traffic cameras, along with labels that indicate the presence and type of objects (vehicles, pedestrians, etc.). The dataset is used to train and test the **YOLOv8** model for detecting these objects in real-time.

- **Data Type:** The primary data type is image or video frames, but metadata may also be included, such as timestamps, camera locations, and weather conditions.
- **Object Labels:** Each object in the dataset is labeled with a class and a bounding box that indicates the position of the object within the image.
  - **Vehicle Classes:** Cars, bikes, buses, trucks, etc.
  - **Pedestrian Classes:** People, children, etc.
  - **Road Signs:** Stop signs, speed limit signs, etc.
  - **Animals:** For detecting animals crossing roads.

### 5.2 Data Collection

For traffic object detection, the dataset could be sourced from several public and private repositories that provide labeled traffic images or video datasets. Some well-known sources include:

- **KITTI Dataset:** A widely used dataset for automotive and traffic-related object detection, which includes images of urban traffic, along with precise 3D annotations.
- **Cityscapes Dataset:** Focuses on semantic segmentation and object detection in urban traffic scenes.
- **COCO (Common Objects in Context):** A large-scale dataset that includes images of various objects, including vehicles and pedestrians, in different contexts.

If the dataset is sourced from a specific local traffic camera network, it will include images or video frames captured at various times of day, under different weather conditions, and from different camera angles.

### 5.3 Data Exploration and Analysis

To perform dataset exploration, several aspects need to be examined:

- **Data Size:**

- **Number of Images/Videos:** The dataset should contain a sufficient number of images or video frames to train the YOLOv8 model effectively. A larger dataset increases the model's ability to generalize across different traffic scenarios.
- **Number of Classes:** The dataset should include a diverse range of classes (vehicles, pedestrians, road signs, etc.) to ensure the model can recognize various traffic-related objects.
- **Data Distribution:**
  - **Class Distribution:** Check if the dataset is imbalanced. For example, if there are significantly more vehicles than pedestrians, the model might learn to detect vehicles better, which could lead to poor performance on pedestrian detection.
  - **Bounding Box Distribution:** The bounding boxes around the objects should be analyzed to ensure they are properly labeled and tight around the objects. Mislabeling or improperly placed bounding boxes can negatively impact model training.
- **Image/Video Quality:**
  - **Resolution:** The resolution of the images and video frames should be checked. Higher resolution provides more detailed information for object detection but requires more computational resources.
  - **Lighting and Weather Conditions:** The dataset should ideally contain samples from different weather conditions (rain, fog, clear skies) and at different times of the day (daylight, dusk, night) to train a robust model.
  - **Camera Angles and Occlusions:** The dataset should ideally include images from different camera angles (e.g., traffic cameras mounted at intersections, elevated cameras) and should account for occlusions (objects blocking others), which are common in real-world traffic scenarios.

## 5.4 Data Preprocessing

Before feeding the dataset into the YOLOv8 model, the following preprocessing steps are generally performed:

- **Image Resizing:** YOLOv8 requires input images to be of a consistent size (e.g., 416x416 or 640x640 pixels). Images may need to be resized while maintaining their aspect ratio or cropping them to fit the required input dimensions.
- **Normalization:** Pixel values are often normalized to a range of [0, 1] by dividing each pixel value by 255. This helps the model converge faster during training.
- **Data Augmentation:** To improve the model's robustness and prevent overfitting, data augmentation techniques can be applied. These techniques include:
  - **Flipping:** Horizontally or vertically flipping the images.
  - **Rotation:** Rotating images to simulate different camera angles.
  - **Brightness/Contrast Adjustments:** Changing the brightness or contrast to simulate different lighting conditions.
  - **Zooming or Cropping:** To simulate occlusions or changes in object size.
- **Label Encoding:** The labels (vehicle, pedestrian, etc.) are converted into numeric values for training.

## 5.5 Exploratory Data Analysis (EDA)

During EDA, visualizations and statistical methods are used to gain insights into the dataset:

- **Class Distribution:** Plot the number of instances of each class (vehicle, pedestrian, etc.) to check for class imbalance.
  - If the dataset has an imbalanced distribution, techniques like class weighting or oversampling/undersampling can be used to address this.
- **Bounding Box Analysis:** Visualize some sample images with bounding boxes to ensure that the objects are correctly labeled and the bounding boxes are tight around the objects.
- **Object Size Distribution:** Analyze the size distribution of the objects in the dataset. Some objects may be very small (pedestrians in the distance), while others may be large (buses or trucks), and the model needs to handle these variations well.
- **Spatial Distribution:** Analyze the spatial distribution of objects in the images. For example, vehicles and pedestrians are often concentrated in specific regions of the image (e.g., vehicles in the lower half, pedestrians near sidewalks).
- **Temporal Analysis (for videos):** If the dataset consists of video frames, analyze the temporal consistency of object labels. Objects in consecutive frames should generally retain their identities, and frame-to-frame motion can be tracked for real-time traffic analysis.

---

## 6. PROJECT FEASIBILITY

### 6.1 Technical Feasibility

The technical feasibility of this project looks at whether the existing technology and infrastructure can support its implementation.

- **Object Detection with YOLOv8:** YOLOv8 (You Only Look Once) is an advanced deep learning model known for real-time object detection. It is suitable for detecting traffic objects such as vehicles, pedestrians, road signs, and animals. Given its speed and accuracy, YOLOv8 is a powerful tool for real-time applications.
- **Data Analysis with Power BI:** Power BI is a robust tool for data analysis and visualization. It will be used to create real-time dashboards and graphs, displaying vehicle counts and traffic density. The integration of Power BI with a MySQL database ensures seamless data storage and retrieval for analysis.
- **System Architecture:** The system will rely on a combination of YOLOv8 for detection, MySQL for data storage, and Power BI for analysis and visualization. This integration supports smooth operation, as each part of the system is robust and scalable.
- **Scalability:** The project is designed to be scalable for future smart city applications. Additional features can be incorporated, such as integrating with physical traffic control systems or expanding the object detection capabilities to include additional traffic-related objects.

### 6.2 Operational Feasibility

Operational feasibility assesses whether the project can be implemented within the operational constraints of the organization or environment.

- **Real-Time Traffic Monitoring:** The project's core functionality is real-time traffic monitoring. YOLOv8's capability to handle real-time object detection ensures that the system can operate continuously without performance degradation.
- **User Interaction:** The system will feature a real-time dashboard that can be accessed by traffic management authorities. The dashboard will display real-time traffic data, including the number of vehicles, pedestrian counts, and detected animals.
- **Data Flow and Reporting:** The integration of Power BI will ensure that the data collected from traffic monitoring will be visualized effectively. The system will allow local authorities to take timely decisions based on the traffic data it generates, such as rerouting vehicles or issuing alerts for detected animals.
- **Maintenance and Upkeep:** The system will require regular updates to the YOLOv8 model for improved accuracy and efficiency. The servers running the real-time detection system must be maintained to avoid downtime.

### 6.3 Economic Feasibility

Economic feasibility looks at the financial aspects of the project, including its cost-effectiveness and potential return on investment.

- **Cost of Technology:** YOLOv8 and Power BI are both open-source tools, with Power BI having a free version. The MySQL database is also open-source. Therefore, the core technologies do not require significant licensing fees. However, cloud storage or on-site infrastructure may involve some costs.
- **Hardware Costs:** The project will need powerful hardware for real-time object detection. High-performance GPUs are necessary for YOLOv8 to run smoothly. Additionally, storage for MySQL databases and the Power BI dashboard setup will require some investment.
- **Operational Costs:** The ongoing costs for the project include cloud service fees (if applicable), server maintenance, and the cost of updating the YOLOv8 model periodically.
- **Return on Investment:** The project contributes to better traffic management, improved road safety, and the potential reduction in traffic congestion. This can lead to cost savings in terms of time, fuel, and public safety. Additionally, it can be extended to smart city applications, which could generate future revenue through government partnerships or data services.
